# 3.3 Balanced Search Trees

2-3 search trees

red-black BS<del>Ts</del>

B-trees

#### 2-3 tree

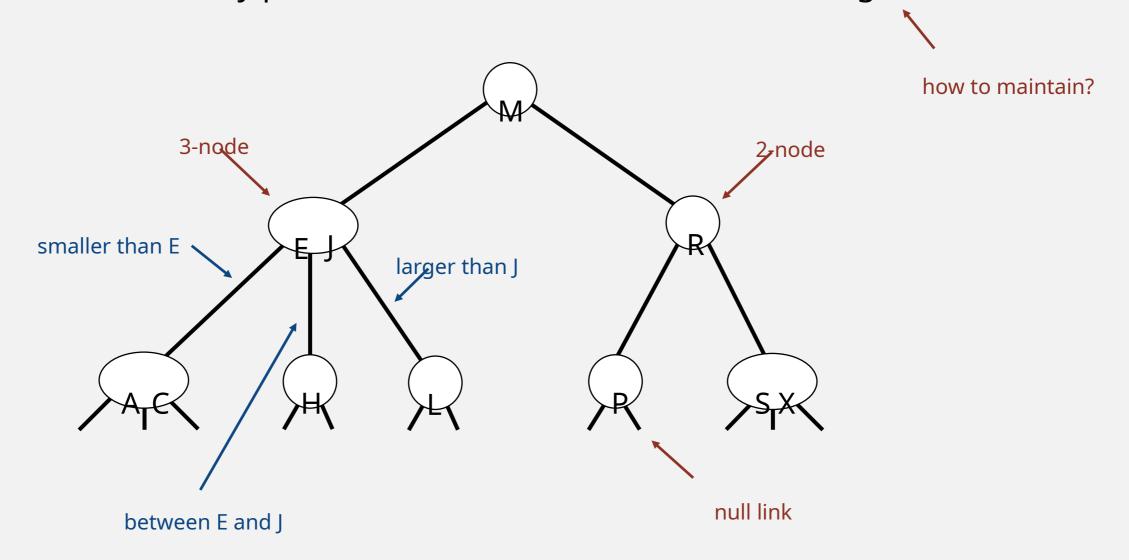

#### Allow 1 or 2 keys per node.

2-node: one key, two children.

3-node: two keys, three children.

Symmetric order. Inorder traversal yields keys in ascending order.

Perfect balance. Every path from root to null link has same length.

### 2-3 tree demo

#### Search.

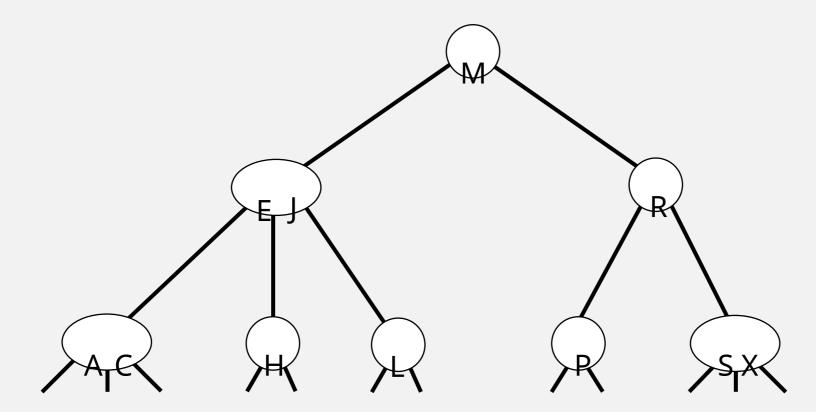

Compare search key against keys in node.

Find interval containing search key.

Follow associated link (recursively).

#### search for H

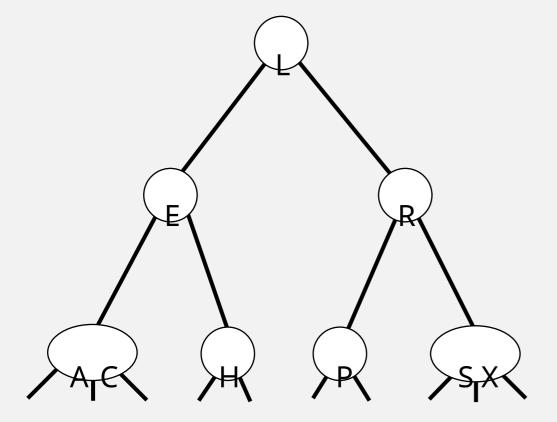

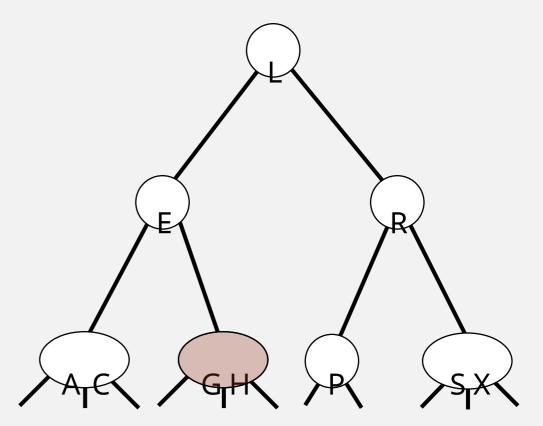

## Insertion into a 2-3 tree

#### Insertion into a 2-node at bottom.

Add new key to 2-node to create a 3-node.

#### insert G

#### Insertion into a 2-3 tree

#### Insertion into a 3-node at bottom.

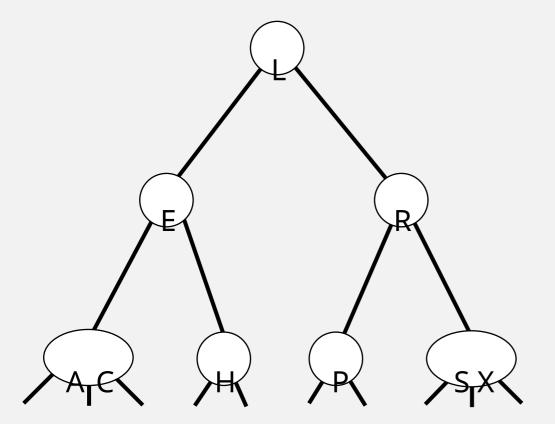

Add new key to 3-node to create temporary 4-node.

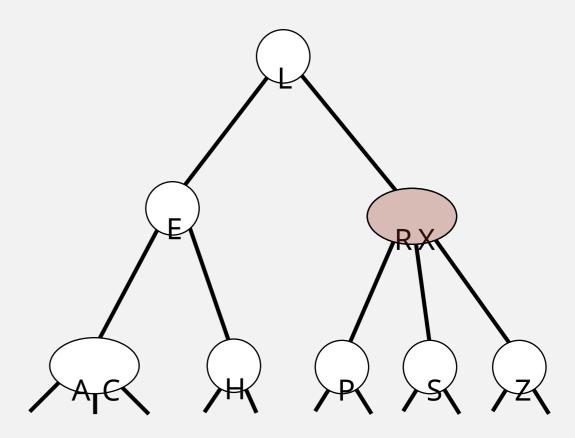

Move middle key in 4-node into parent.

Repeat up the tree, as necessary.

☐ If you reach the root and it's a 4-node, split it into three 2-nodes.

#### insert Z

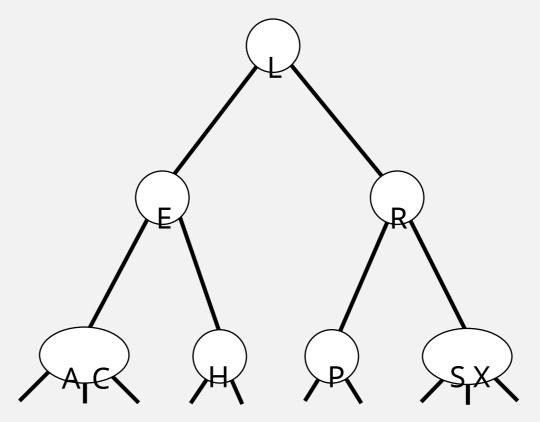

# 2-3 tree construction demo

#### insert S

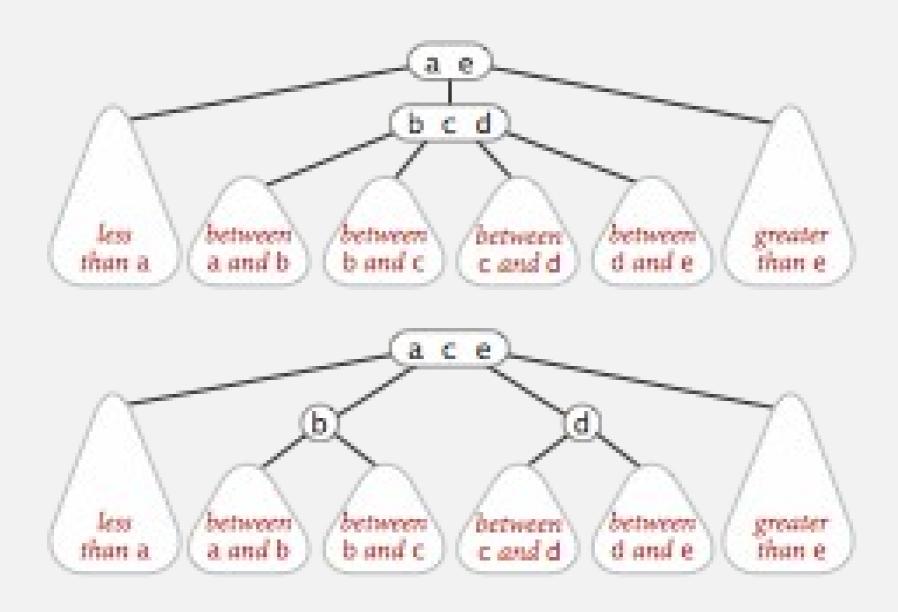

#### **2-3 tree**

### Local transformations in a 2-3 tree

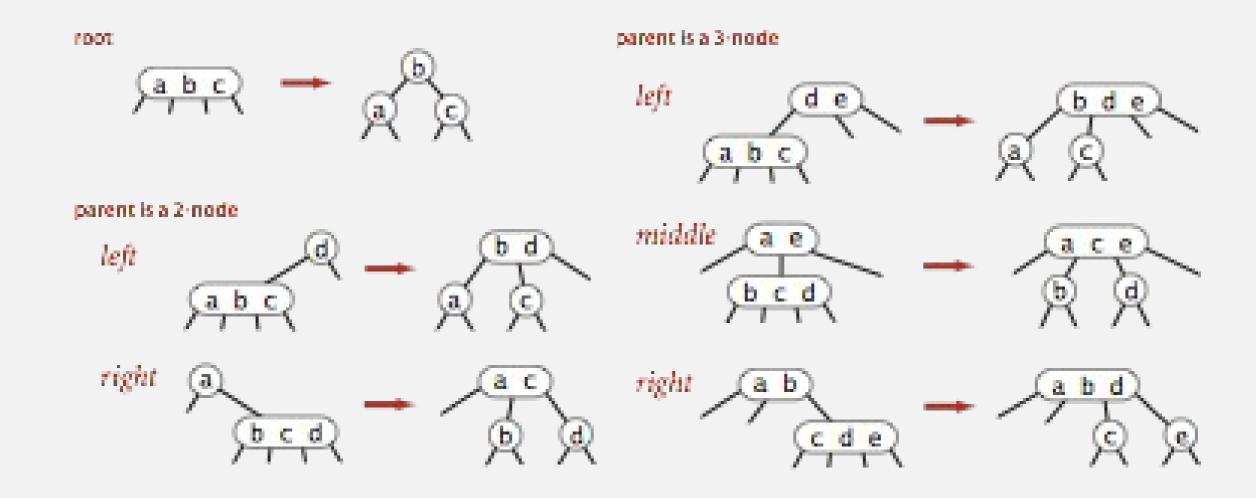

Splitting a 4-node is a local transformation: constant number of operations.

# Global properties in a 2-3 tree

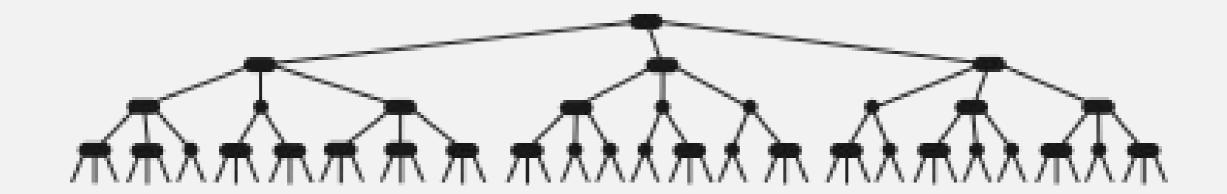

Invariants. Maintains symmetric order and perfect balance.

Pf. Each transformation maintains symmetric order and perfect balance.

# 2-3 tree: performance

Perfect balance. Every path from root to null link has same length.

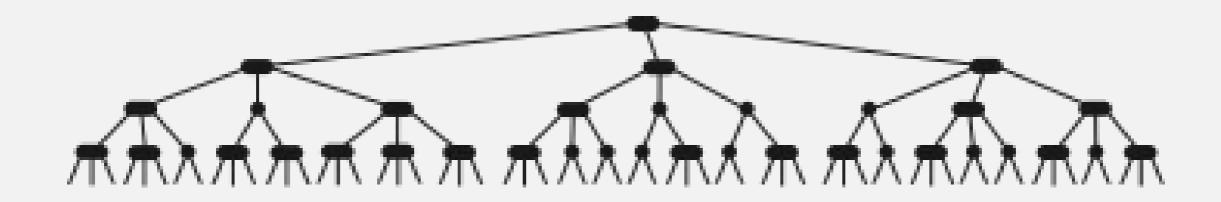

#### Tree height.

- Worst case:
- Best case:

# 2-3 tree: performance

Perfect balance. Every path from root to null link has same length.

#### Tree height.

Worst case:  $\lg N$ . [all 2-nodes]

Best case:  $\log_3 N \approx .631 \lg N$ . [all 3-nodes]

Between 12 and 20 for a million nodes.

Between 18 and 30 for a billion nodes.

Bottom line. Guaranteed logarithmic performance for search and insert.

# ST implementations: summary

implementation	guarantee			average case			ordered	key
	search	insert	delete	search hit	insert	delete	ops?	interface
sequential search (unordered list)	N	N	N	$^{1}\!/_{2}N$	N	$^{1}\!/_{2}N$		equals()
binary search (ordered array)	$\lg N$	N	N	lg N	½ N	$^{1}\!/_{2}N$	$\checkmark$	compareTo()
BST	N	N	N	1.39 lg <i>N</i>	1.39 lg <i>N</i>	$\sqrt{N}$	$\checkmark$	compareTo()
2-3 tree	$c \lg N$	$c \lg N$	$c \lg N$	$c \lg N$	$c \lg N$	$c \lg N$	$\checkmark$	compareTo()

constant c depend upon implementation

## 2-3 tree: implementation?

#### Direct implementation is complicated, because:

```
Maintaining multiple node types is cumbersome.
Need multiple compares to move down tree.
Need to move back up the tree to split 4-nodes.
Large number of cases for splitting.
```

#### fantasy code

```
public void put(Key key, Value val)
{
   Node x = root;
   while (x.getTheCorrectChild(key) != null)
   {
      x = x.getTheCorrectChildKey();
      if (x.is4Node()) x.split();
   }
   if (x.is2Node()) x.make3Node(key, val);
   else if (x.is3Node()) x.make4Node(key, val);
}
```

Bottom line. Could do it, but there's a better way.

# 3.3 Balanced Search Trees

- 2-3 search trees
- ► red-black BSTs

B-trees

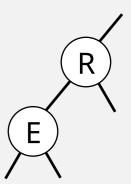

# How to implement 2-3 trees with binary trees?

### Challenge. How to represent a 3 node?

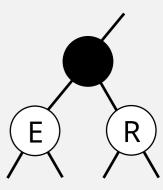

#### Approach 1: regular BST.

- No way to tell a 3-node from a 2-node.
- Cannot map from BST back to 2-3 tree.

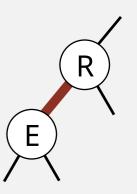

#### Approach 2: regular BST with "glue" nodes.

- ☐ Wastes space, wasted link.
- Code probably messy.

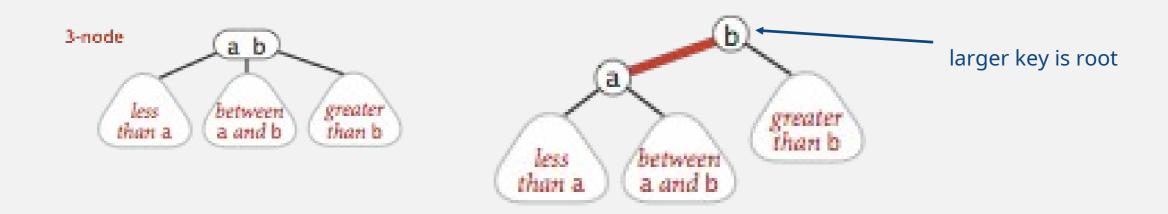

### Approach 3: regular BST with red "glue" links.

- Widely used in practice.
- Arbitrary restriction: red links lean left.

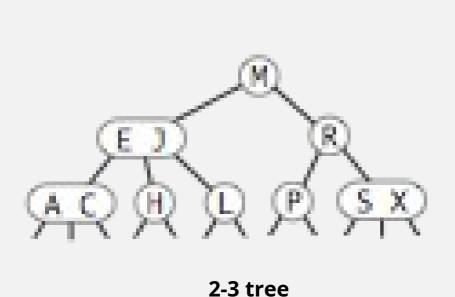

# Left-leaning red-black BSTs (Guibas-Sedgewick 1979 and Sedgewick 2007)

- 1. Represent 2–3 tree as a BST.
- 2. Use "internal" left-leaning links as "glue" for 3–nodes.

red links "glue"

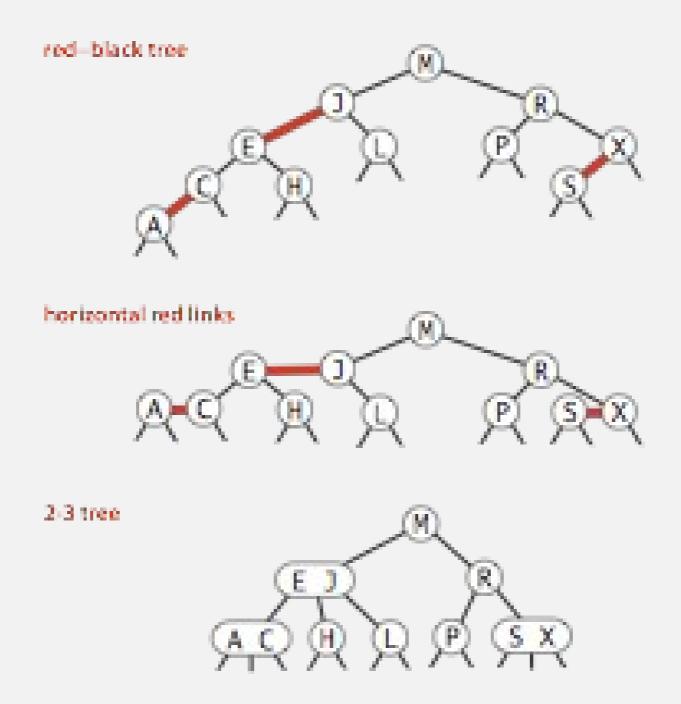

2-nodes and 3-nodes nodes within a 3-node

black links connect

# Left-leaning red-black BSTs: 1-1 correspondence with 2-3 trees

Key property. 1–1 correspondence between 2–3 and LLRB.

# An equivalent definition

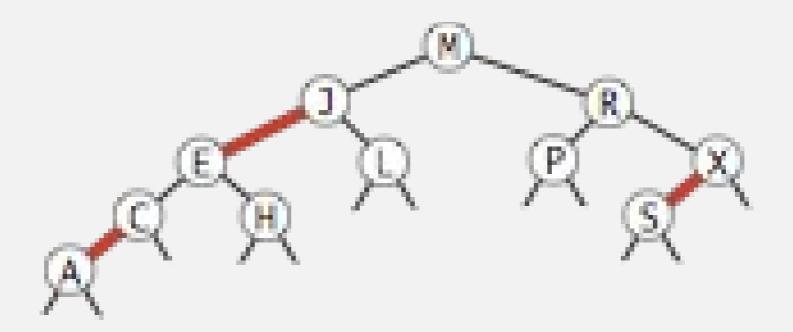

#### A BST such that:

No node has two red links connected to it.

Every path from root to null link has the same number of black links.

Red links lean left.

"perfect black balance"

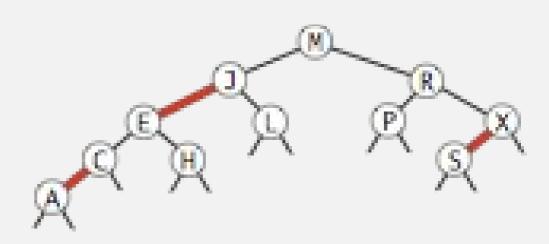

# Search implementation for red-black BSTs

Observation. Search is the same as for elementary BST (ignore color).

but runs faster because of better balance

```
public Val get(Key key)
 Node x = root;
 while (x != null)
   int cmp = key.compareTo(x.key);
        (cmp < 0) x = x.left;
   else if (cmp > 0) x = x.right;
   else if (cmp == 0) return x.val;
 return null;
```

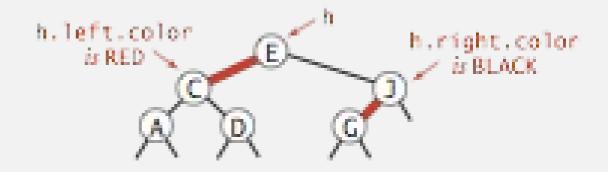

Remark. Most other ops (e.g., floor, iteration, selection) are also identical.

# Red-black BST representation

Each node is pointed to by precisely one link (from its parent)  $\Rightarrow$  can encode color of links in nodes.

```
private static final boolean RED = true;
private static final boolean BLACK = false;
private class Node
 Key key;
 Value val;
 Node left, right;
 boolean color; // color of parent link
private boolean isRed(Node x)
 if (x == null) return false;
                                         null links are black
 return x.color == RED;
```

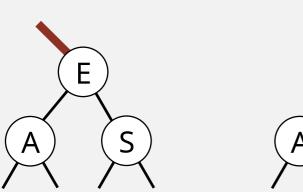

Basic strategy. Maintain 1-1 correspondence with 2-3 trees.

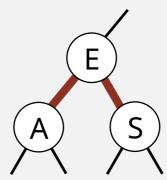

#### During internal operations, maintain:

Perfect black balance.

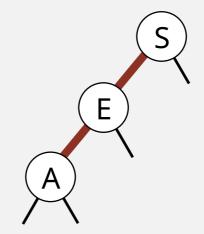

[ but not necessarily color invariants ]

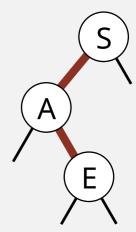

right-leaning red link

two red children (a temporary 4-node)

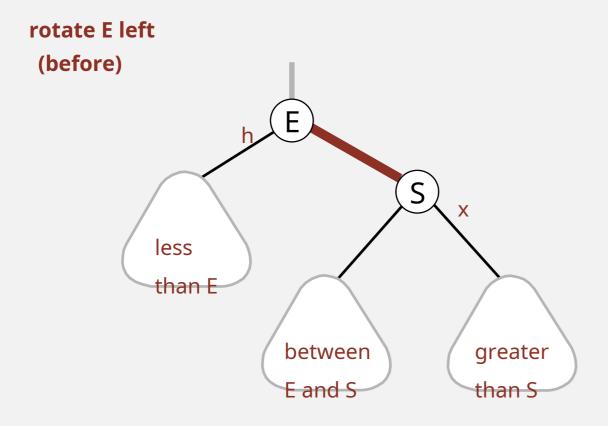

left-left red (a temporary 4-node)

left-right red (a temporary 4-node)

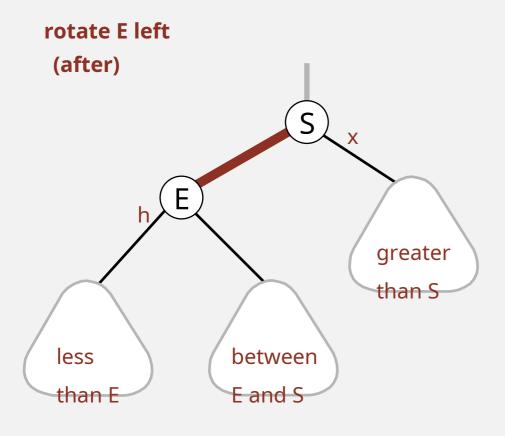

How? Apply elementary red-black BST operations: rotation and color flip.

Left rotation. Orient a (temporarily) right-leaning red link to lean left.

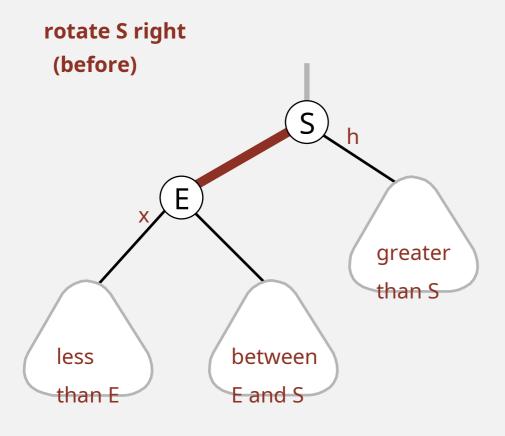

```
private Node rotateLeft(Node h)
{
    assert isRed(h.right);
    Node x = h.right;
    h.right = x.left;
    x.left = h;
    x.color = h.color;
    h.color = RED;
    return x;
}
```

Left rotation. Orient a (temporarily) right-leaning red link to lean left.

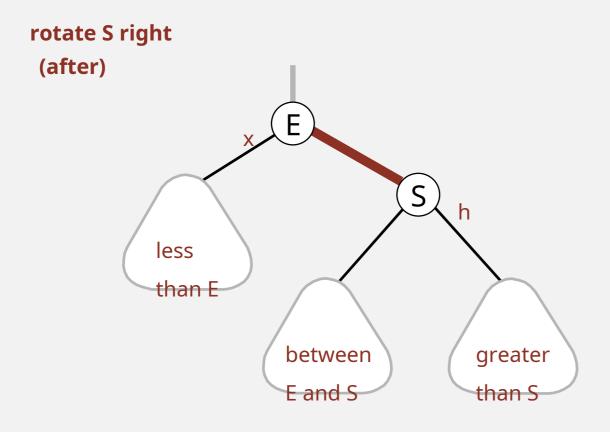

```
private Node rotateLeft(Node h)
{
    assert isRed(h.right);
    Node x = h.right;
    h.right = x.left;
    x.left = h;
    x.color = h.color;
    h.color = RED;
    return x;
}
```

Right rotation. Orient a left-leaning red link to (temporarily) lean right.

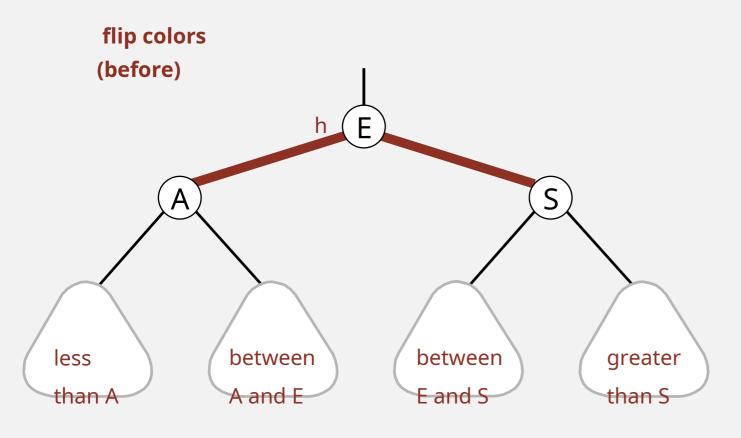

```
private Node rotateRight(Node h)
{
    assert isRed(h.left);
    Node x = h.left;
    h.left = x.right;
    x.right = h;
    x.color = h.color;
    h.color = RED;
    return x;
}
```

Right rotation. Orient a left-leaning red link to (temporarily) lean right.

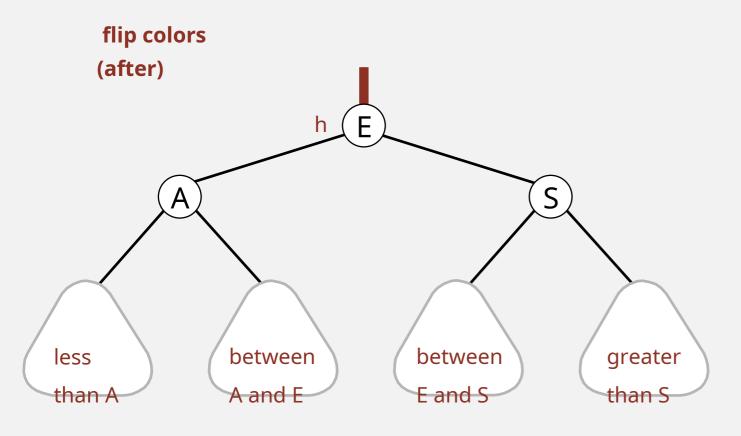

```
private Node rotateRight(Node h)
{
    assert isRed(h.left);
    Node x = h.left;
    h.left = x.right;
    x.right = h;
    x.color = h.color;
    h.color = RED;
    return x;
}
```

Color flip. Recolor to split a (temporary) 4-node.

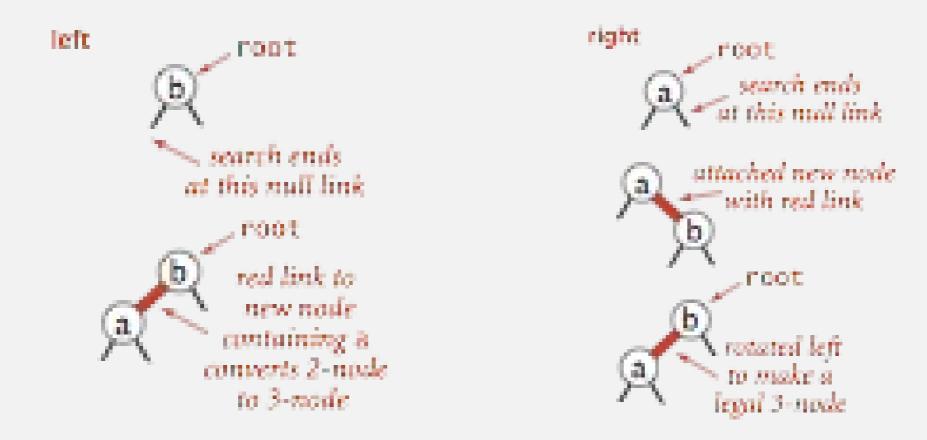

```
private void flipColors(Node h)
{
   assert !isRed(h);
   assert isRed(h.left);
   assert isRed(h.right);
   h.color = RED;
   h.left.color = BLACK;
   h.right.color = BLACK;
}
```

Color flip. Recolor to split a (temporary) 4-node.

```
private void flipColors(Node h)
{
   assert !isRed(h);
   assert isRed(h.left);
   assert isRed(h.right);
   h.color = RED;
   h.left.color = BLACK;
   h.right.color = BLACK;
}
```

Warmup 1. Insert into a tree with exactly 1 node.

#### Insertion in a LLRB tree

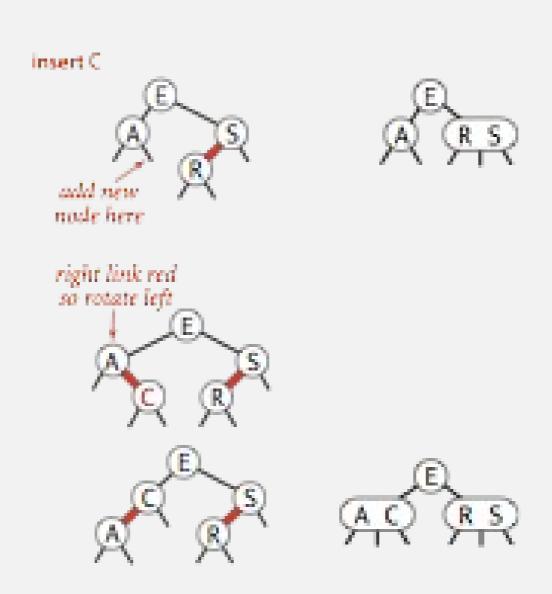

Case 1. Insert into a 2-node at the bottom.

Do standard BST insert; color new link red.

to maintain symmetric order and perfect black balance

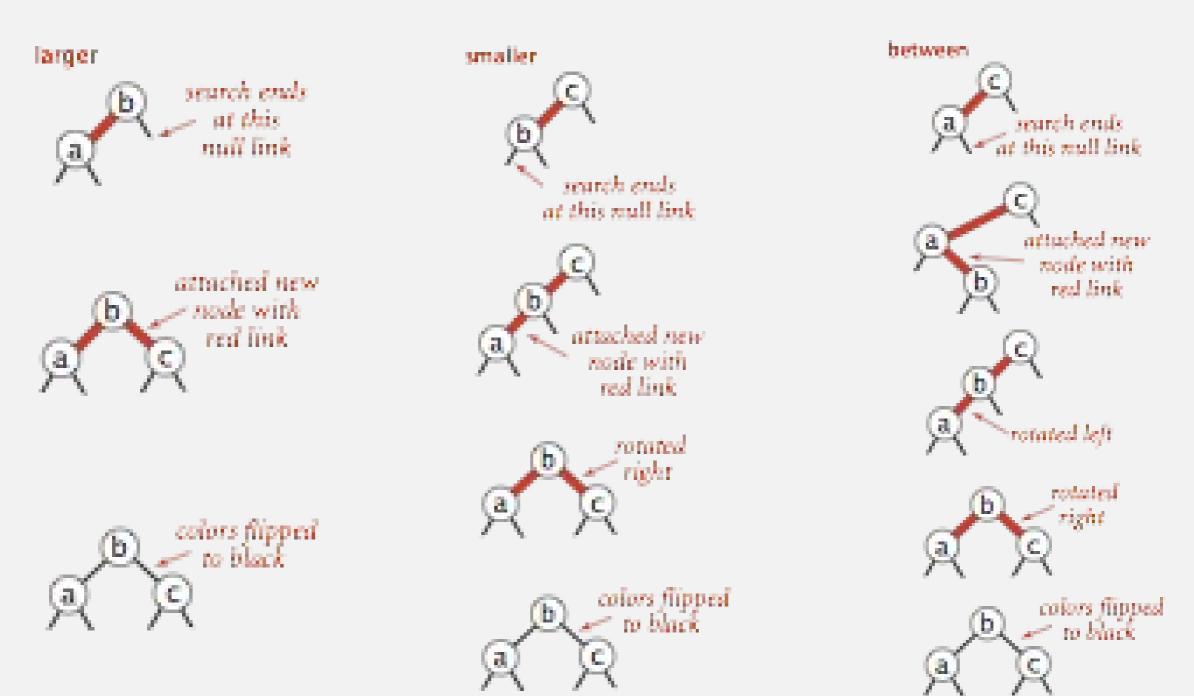

If new red link is a right link, rotate left.

to fix color invariants

#### Insertion in a LLRB tree

## Warmup 2. Insert into a tree with exactly 2 nodes.

#### Insertion in a LLRB tree

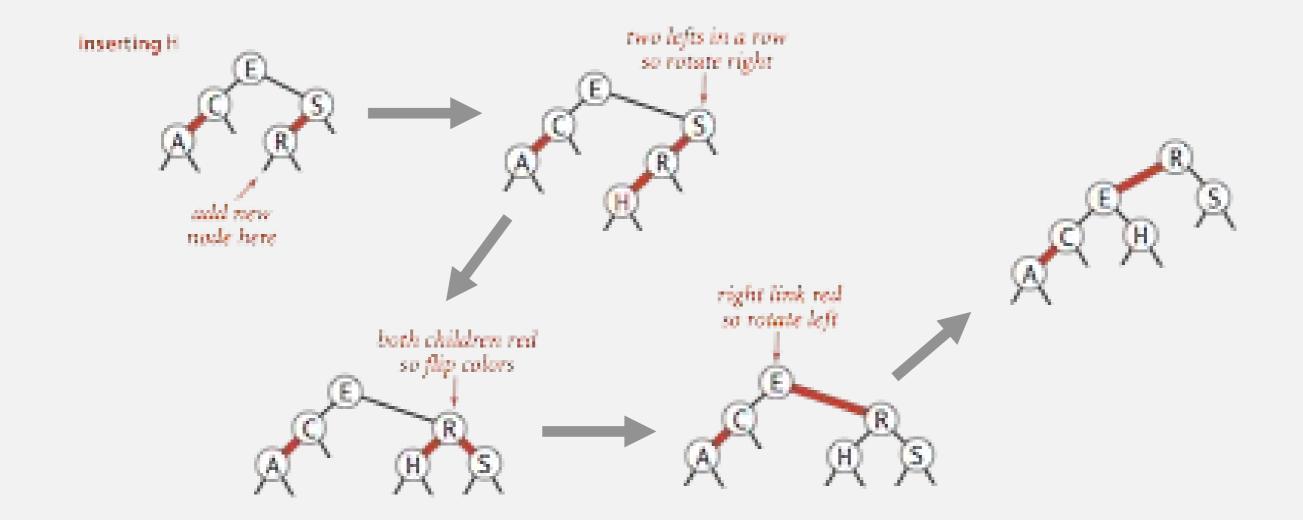

Case 2. Insert into a 3-node at the bottom.

Do standard BST insert; color new link red.

Rotate to balance the 4-node (if needed).

Flip colors to pass red link up one level.

Rotate to make lean left (if needed).

# Insertion in a LLRB tree: passing red links up the tree

Case 2. Insert into a 3-node at the bottom.

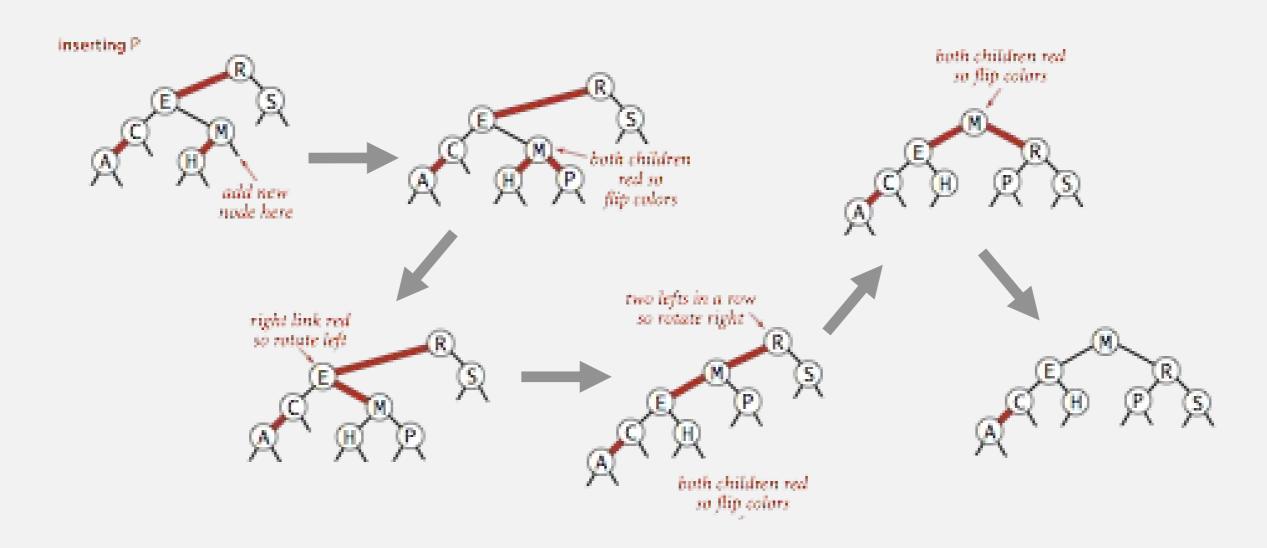

Do standard BST insert; color new link red.

Rotate to balance the 4-node (if needed).

Flip colors to pass red link up one level.

Rotate to make lean left (if needed).

Repeat case 1 or case 2 up the tree (if needed).

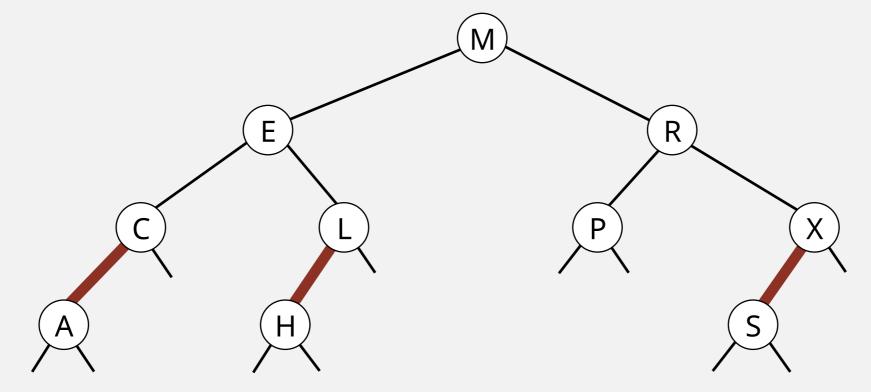

# Red-black BST construction demo

#### insert S

#### red-black BST

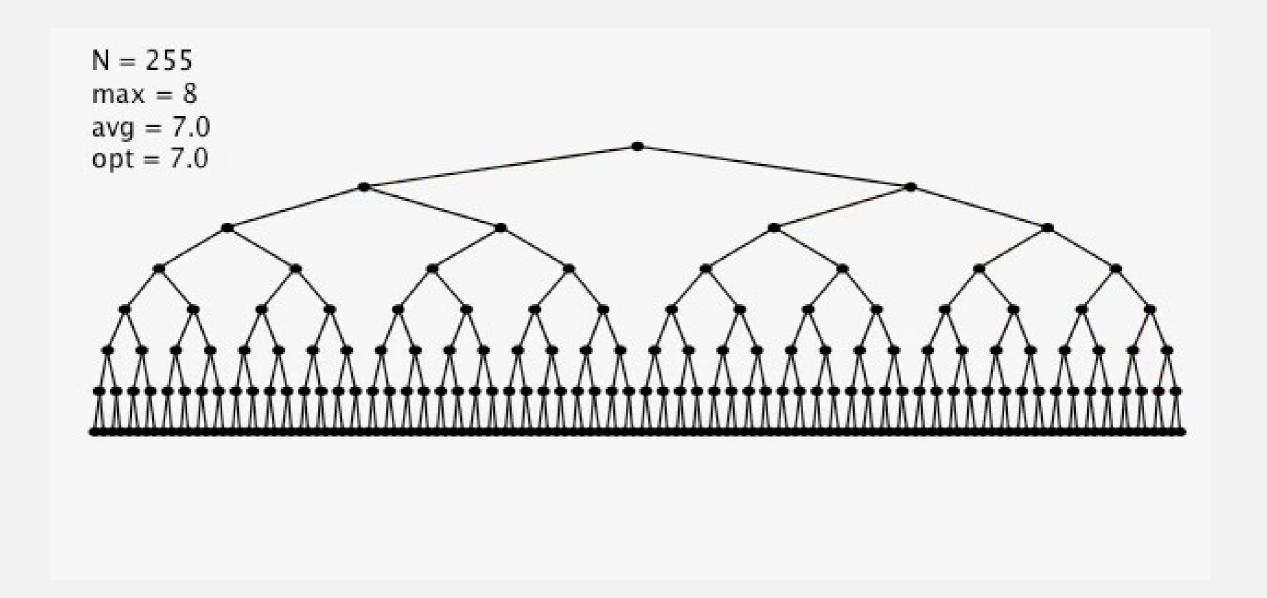

#### Insertion in a LLRB tree: Java implementation

if (isRed(h.left) && isRed(h.right)) flipColors(h); only a few extra lines of code provides near-perfect balance

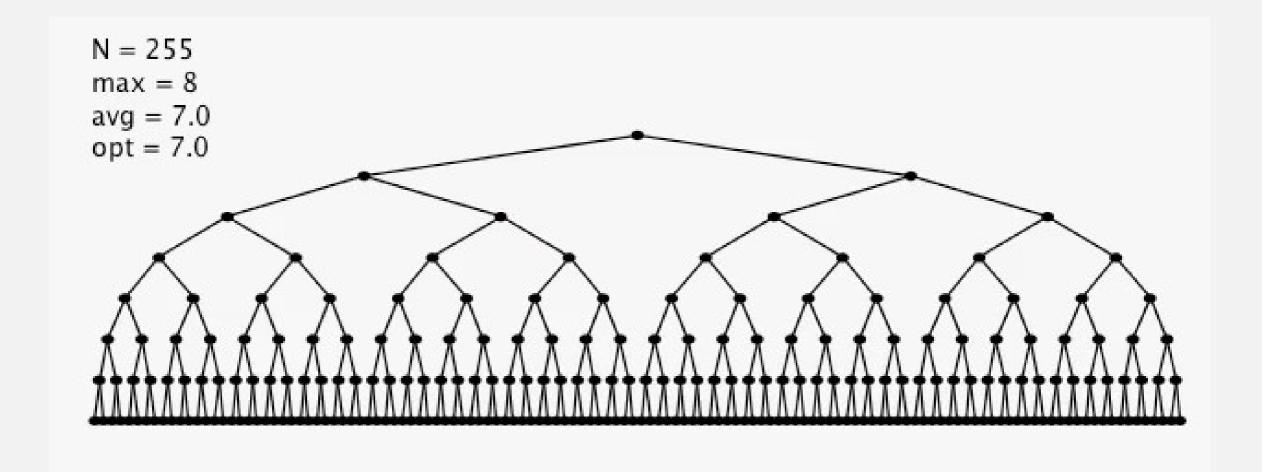

#### Same code for all cases. Right child red, left child black: rotate left. Left child, left-left grandchild red: rotate right. left rotate. Both children red: flip colors. rotate flipcolors private Node put(Node h, Key key, Value val) insert at bottom if (h == null) return new Node(key, val, RED); (and color it red) int cmp = key.compareTo(h.key); (cmp < 0) h.left = put(h.left, key, val);else if (cmp > 0) h.right = put(h.right, key, val); else if (cmp == 0) h.val = val;lean left balance 4-node if (isRed(h.right) && !isRed(h.left)) h = rotateLeft(h); split 4-node if (isRed(h.left) && isRed(h.left.left)) h = rotateRight(h);

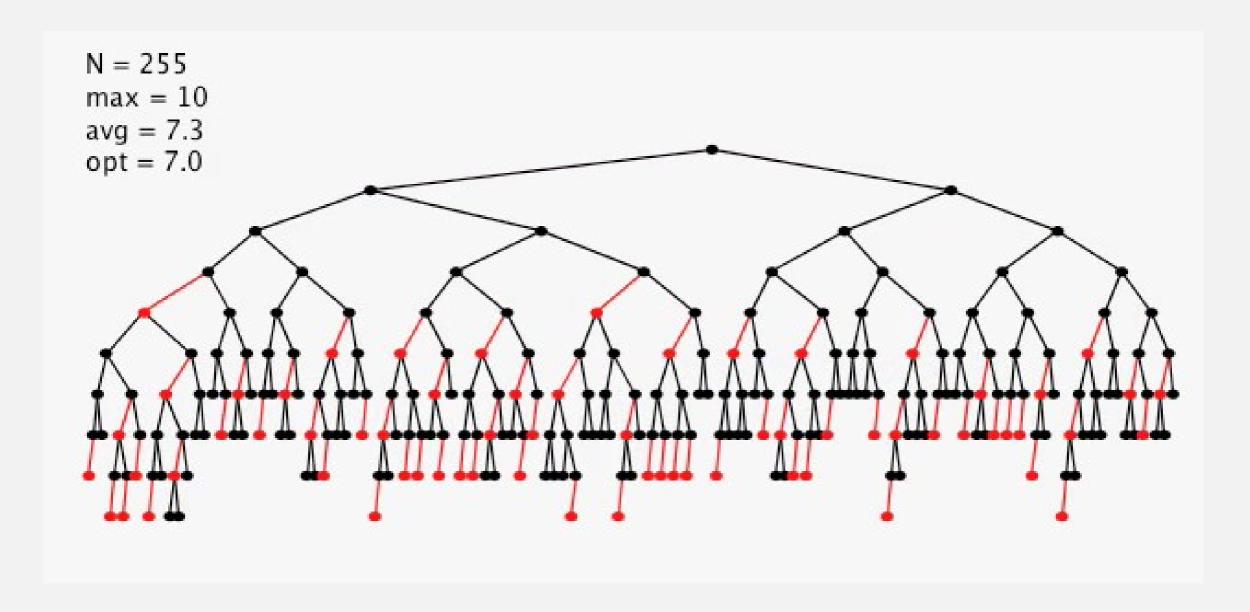

#### Insertion in a LLRB tree: visualization

255 insertions in ascending order

#### Insertion in a LLRB tree: visualization

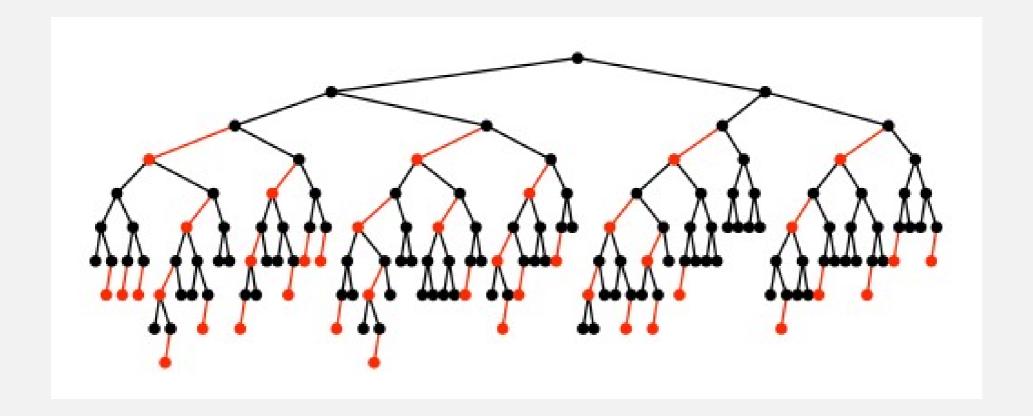

#### 255 random insertions

#### Balance in LLRB trees

Proposition. Height of tree is  $\leq 2 \lg N$  in the worst case.

Pf.

- Every path from root to null link has same number of black links.
- Never two red links in-a-row.

Property. Height of tree is  $\sim 1.0 \lg N$  in typical applications.

# 3.3 Balanced Search Trees

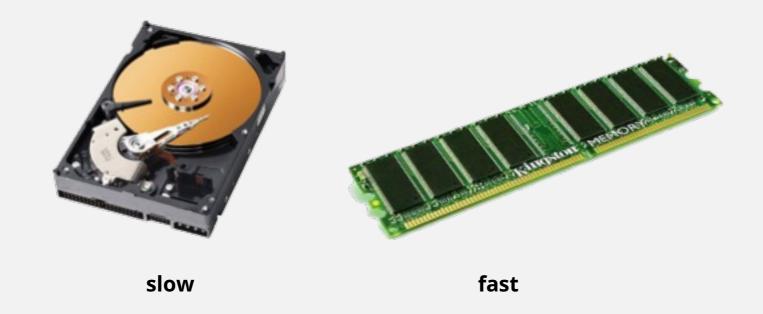

2-3 search trees

red-black BSTs

B-trees

#### File system model

Page. Contiguous block of data (e.g., a file or 4,096-byte chunk). Probe. First access to a page (e.g., from disk to memory).

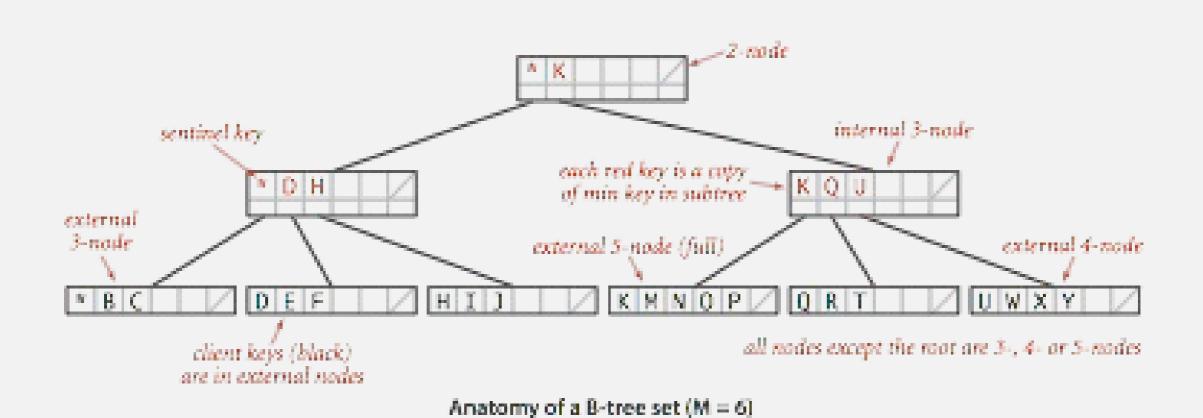

Property. Time required for a probe is much larger than time to access data within a page.

Cost model. Number of probes.

Goal. Access data using minimum number of probes.

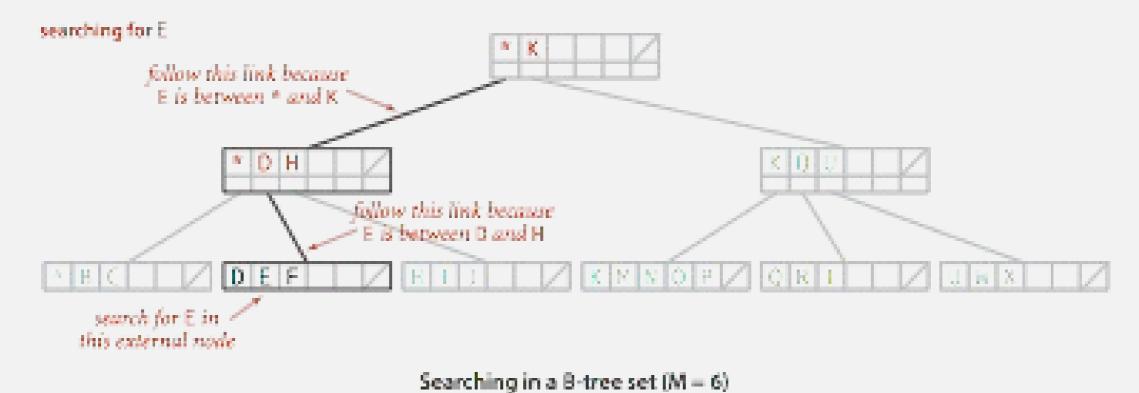

#### B-trees (Bayer-McCreight, 1972)

B-tree. Generalize 2-3 trees by allowing up to *M* - 1 key-link pairs per node.
 At least 2 key-link pairs at root.
 At least *M* / 2 key-link pairs in other nodes.
 External nodes contain client keys.
 Internal nodes contain copies of keys to guide search.

## Searching in a B-tree

Start at root.Find interval for search key and take corresponding link.Search terminates in external node.

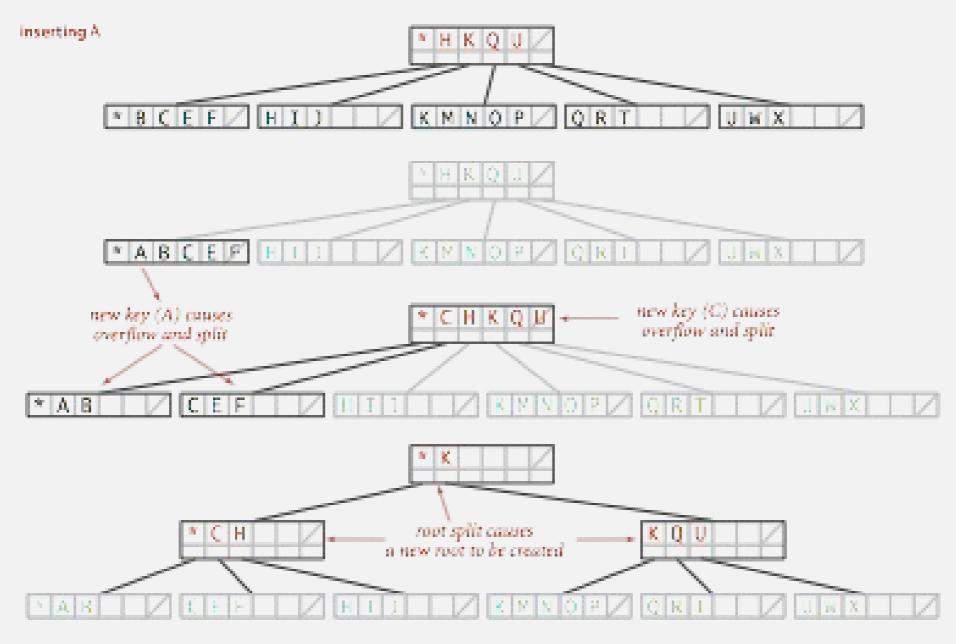

#### Insertion in a B-tree

Search for new key.

Insert at bottom.

 $\square$  Split nodes with M key-link pairs on the way up the tree.

Inserting a new key into a B-tree set

#### Balance in B-tree

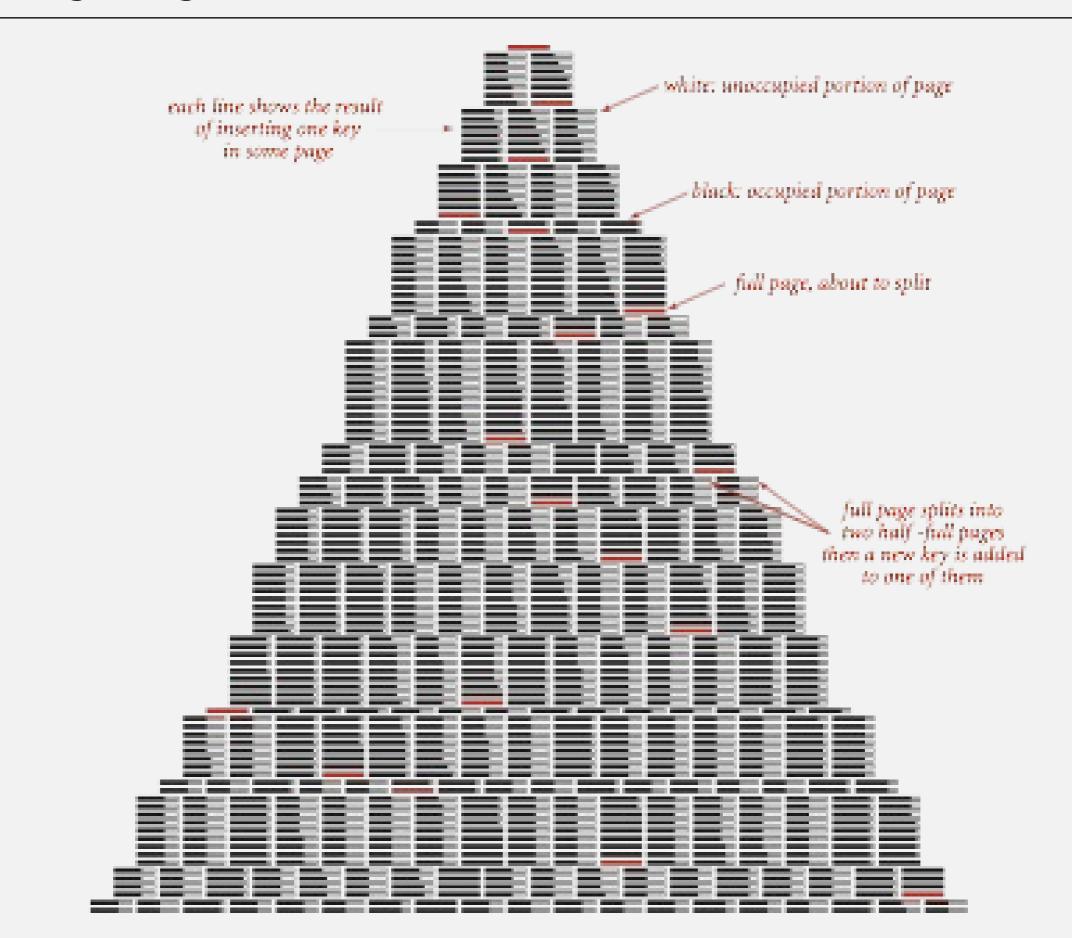

Proposition. A search or an insertion in a B-tree of order M with N keys requires between  $\log_{M-1} N$  and  $\log_{M/2} N$  probes.

Pf. All internal nodes (besides root) have between M/2 and M-1 links.

In practice. Number of probes is at most 4. M = 1024; N = 62 billion  $\log_{M/2} N \le 4$ 

Optimization. Always keep root page in memory.

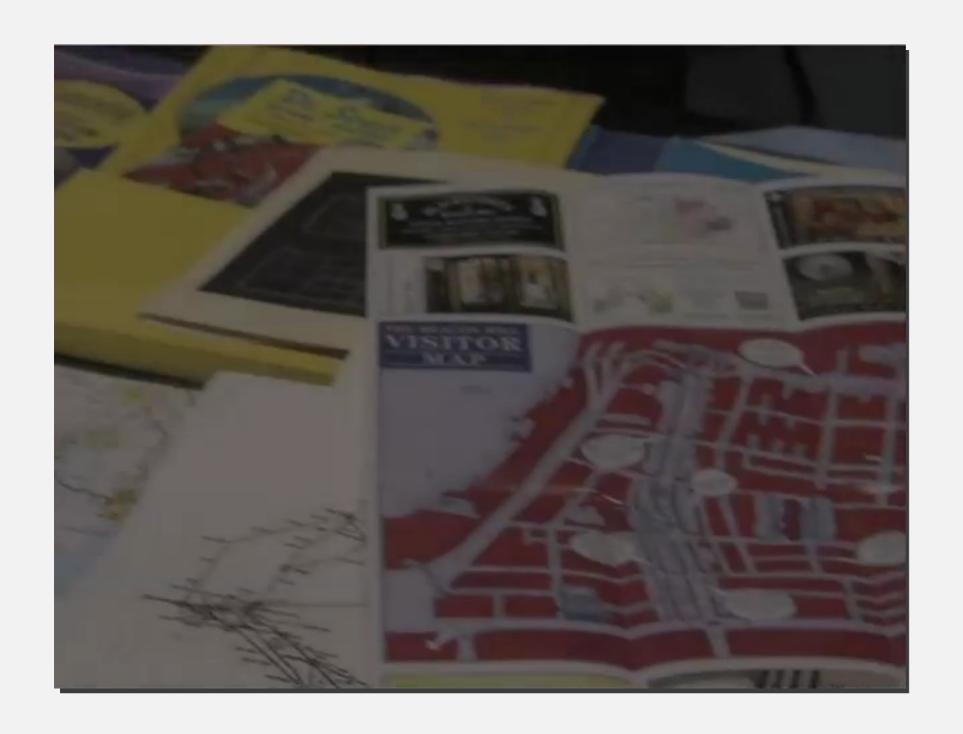

## Building a large B tree

# Balanced trees in the wild

Red	l-black trees are widely used as system symbol tables.
	Java: java.util.TreeMap, java.util.TreeSet.
	C++ STL: map, multimap, multiset.
	Linux kernel: completely fair scheduler, linux/rbtree.h.
	Emacs: conservative stack scanning.
	ee variants. B+ tree, B*tree, B# tree,
<b>D</b> -U	ees (and variants) are widely used for file systems and databases.
	Windows: NTFS.
	Mac: HFS, HFS+.
	Linux: ReiserFS, XFS, Ext3FS, JFS.
	Databases: ORACLE, DB2, INGRES, SQL, PostgreSQL.

## Red-black BSTs in the wild

Common sense. Sixth sense.
Together they're the
FBI's newest team.

#### Red-black BSTs in the wild

#### ACT FOUR

FADE IN:

#### 48 INT. FBI HO - NIGHT

48

Antonio is at THE COMPUTER as Jess explains herself to Nicole and Pollock. The CONFERENCE TABLE is covered with OPEN REFERENCE BOOKS, TOURIST GUIDES, MAPS and REAMS OF PRINTOUTS.

JESS

It was the red door again.

POLLOCK

I thought the red door was the storage container.

**JESS** 

But it wasn't red anymore. It was black.

ANTONIO

So red turning to black means... what?

POLLOCK

Budget deficits? Red ink, black ink?

NICOLE

Yes. I'm sure that's what it is. But maybe we should come up with a couple other options, just in case.

Antonio refers to his COMPUTER SCREEN, which is filled with mathematical equations.

ANTONIO

It could be an algorithm from a binary search tree. A red-black tree tracks every simple path from a node to a descendant leaf with the same number of black nodes.

JESS

Does that help you with girls?
